Celsius to Fahrenheit

Celsius and Fahrenheit are two important scales to measure temperature. These are two important units of the temperature scale. The temperature in the centigrade scale is expressed in degrees Celsius. The temperature in the Celsius scale is denoted by °C. The temperature in the Fahrenheit scale is expressed in degrees Fahrenheit. The temperature in the Fahrenheit scale is denoted by °F. The relationship between these two scales is:

$$(9/5)*C=F-32$$

Therefore, the formula to convert a given temperature from Celsius scale to Fahrenheit scale is:

$$F=(9/5)*C+32$$

We will use this formula to convert a given temperature from Celsius scale to Fahrenheit scale.
For example:
Temperature in Celsius scale = 25 °C

$$F=((9/5)\times25)+32$$
$$F=77$$

Equivalent temperature in Fahrenheit scale = 77.0 °F

Algorithm:

Step 1: Start

Step 2: Read the value of temperature to be converted from the user

Step 3: Assign the value to a variable, say ‘cel’

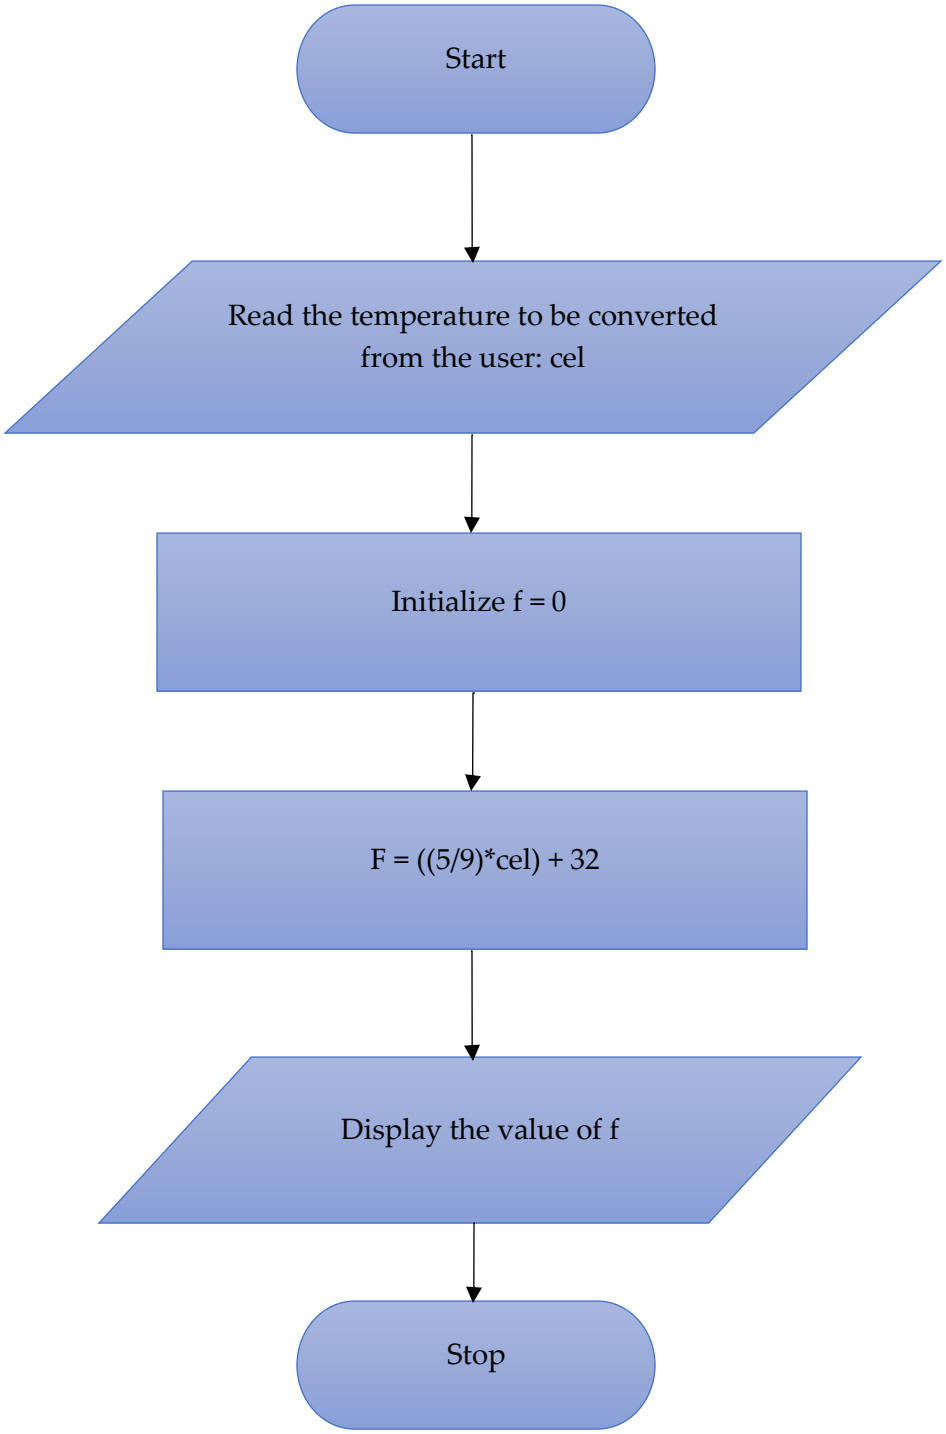

Step 4: Initialize f = 0

Step 5: f = ((5/9) * cel) + 32

Step 6: Display f

Step 7: Stop

Flowchart:

Start
Read the temperature to be converted from the user: cel
Initialize f = 0
F = ((5/9)*cel) + 32
Display the value of f
Stop

Code:

```
1. #include<stdio.h>
2. void main()
3.  {
4.                  float f, cel;
5.                  scanf("%f", &cel);
6.                  f =( (cel*9)/5)+32;
7.                  printf("\n\n Temperature in Fahrenheit is:  %f", f);
8.   }
```
